ABSTRACT

This research proposes the development of a dynamic sign detection system using computer vision to enhance the recognition of Tamil Sign Language (TSL) gestures for the hearing-impaired in Sri Lanka. The system will utilize webcam input to identify and interpret dynamic TSL gestures in real time, employing OpenCV and Mediapipe for dataset creation and preprocessing. By focusing on capturing the fluidity of transitional movements, the project addresses a critical need for accurate gesture recognition in diverse environments, laying a technical foundation for improved communication accessibility.

The methodology includes training Long Short-Term Memory (LSTM) networks to handle the complexities of transitional movements, enhanced by innovative preprocessing techniques such as key point extraction and encoding for robust accuracy. A backend API will be developed to facilitate real-time processing, ensuring the system can adapt to varying user inputs and environmental conditions. This approach aims to build a reliable technical infrastructure that supports the recognition of dynamic TSL gestures with high precision.

The proposed system seeks to provide a scalable solution that can be integrated into broader applications, contributing to the empowerment of the hearing-impaired community in education and daily life. By leveraging advanced computer vision tools and machine learning, the research offers a foundation for future enhancements, promoting inclusivity and accessibility. This development process focuses on creating a robust, standalone system that can serve as a stepping stone for further innovation in TSL recognition technologies.

1. INTRODUCTION

Tamil Sign Language (TSL) is a dynamic visual communication system that supports millions of hearing-impaired individuals worldwide, particularly in Sri Lanka, where it serves as a critical tool for expression and interaction. With an estimated 300,000 people affected by hearing impairments in the country and a growing global recognition of sign language needs [12], the demand for effective TSL recognition is rising. TSL, encompassing a variety of gestures including transitional movements and contextual signs, accounts for a significant portion of communication among the hearing-impaired, though its lack of standardization poses challenges. The prevalence of communication barriers is expected to increase with population growth, presenting a pressing issue for education, social inclusion, and healthcare systems supporting this community.

Early and accurate detection of TSL gestures is essential for enhancing communication and enabling timely access to educational and assistive resources, which can improve quality of life and social participation. However, conventional approaches, such as manual interpretation by trained signers or pre-recorded video tutorials, often identify gesture patterns only at advanced stages of proficiency or misinterpret subtle dynamics. These methods are labor-intensive, require expert supervision, and are not easily accessible in low-resource or home-based settings. Consequently, there is a growing need for affordable, non-invasive, and scalable recognition tools that can interpret TSL gestures in real time, particularly in diverse and uncontrolled environments.

Recent advancements in artificial intelligence (AI) and computer vision have paved the way for innovative gesture recognition systems. Research indicates that dynamic hand movements, finger configurations, and transitional sequences can act as key indicators of TSL proficiency and intent. Hearing-impaired individuals using TSL may exhibit variations in gesture speed, hand positioning, and sequence fluidity, which are challenging for manual monitoring but can be captured and analyzed using AI-driven techniques such as OpenCV and Mediapipe. These subtle markers offer potential for developing systems that support real-time communication.

Despite these promising developments, existing computer vision systems often focus on single modalities, such as static hand poses, or are tested in controlled laboratory settings, limiting their effectiveness in real-world applications. Few solutions integrate multimodal features—combining hand tracking, gesture transitions, and contextual analysis—to provide a comprehensive assessment of TSL. Moreover, many models operate as “black boxes,” providing limited insight into the features driving recognition, which reduces trust and adoption among users and developers.

This project component addresses these gaps by proposing a dynamic sign detection system using computer vision that leverages hand tracking, gesture sequence analysis, and real-time processing.

By fusing these digital biomarkers, the system aims to deliver accurate TSL recognition in a transparent, accessible, and non-invasive manner. Designed for integration into platforms like "SignSight," the proposed solution will empower the hearing-impaired community, educators, and developers to enhance communication accessibility, fostering greater inclusion in education and daily life.

1.1 BACKGROUND AND LITERATURE

Tamil Sign Language (TSL) is a cornerstone of communication for the hearing-impaired community in Sri Lanka, where approximately 300,000 individuals rely on it for daily interactions, education, and social engagement [12]. This visual language employs a sophisticated array of dynamic gestures, including hand shapes, finger orientations, and smooth transitional movements, to convey meaning with contextual depth. Unlike spoken languages, TSL's reliance on motion and spatial relationships presents unique challenges for recognition, compounded by the absence of a standardized lexicon [10]. This growing need for accessible communication tools highlights the urgency of developing advanced systems to support the hearing-impaired population.

Historically, TSL recognition has depended on manual interpretation by trained signers or the use of pre-recorded video resources, both of which have significant limitations. Manual interpretation is resource-heavy, requiring constant human presence, while video-based learning lacks the flexibility to adapt to real-time conversations or diverse settings. These methods often fail to account for the fluidity of TSL gestures, such as the subtle transitions between signs, leading to miscommunication in dynamic environments [4], [6]. The demand for automated, scalable solutions has thus emerged as a priority, particularly in regions where professional support is scarce, driving interest in computer vision technologies [5], [8].

The field of computer vision has made notable strides in gesture recognition, offering potential applications for TSL. Research by Kapoor et al. [1] utilized Mediapipe to track hand landmarks, achieving an 86% accuracy rate in identifying continuous gesture patterns, providing a viable starting point for TSL systems. Similarly, Nair and Iyer [2] explored LSTM networks to model temporal gesture sequences, reporting a 91% success rate in predicting multi-frame transitions, which aligns with TSL's dynamic characteristics. These studies underscore the feasibility of using video-based analysis and machine learning to capture the nuances of sign language, paving the way for real-time recognition tools [7].

Further advancements have focused on enhancing the robustness of gesture detection through preprocessing techniques. Work by Suresh and Reddy [3] demonstrated that OpenCV-based key point extraction improved recognition accuracy by 12% under varying lighting conditions, a critical consideration for TSL use in natural settings. However, most existing systems are designed for

controlled environments or focus on static poses [4], [5], neglecting the real-time, context-aware analysis required for TSL. This gap, combined with the limited interpretability of many deep learning models [9], restricts their practical utility and user trust, necessitating a more integrated approach [11].

This project builds on these insights by proposing a dynamic sign detection system that leverages computer vision to address TSL's unique challenges. By integrating OpenCV and Mediapipe for data collection [1], LSTM networks for sequence modeling [2], and a transparent recognition framework [9], the system aims to provide a reliable, accessible solution. The literature suggests that combining real-time processing with robust preprocessing can overcome current limitations [3], [7], offering a foundation for future enhancements. This approach not only supports the immediate needs of the TSL community [12] but also sets the stage for broader applications in sign language technology [10], [11].

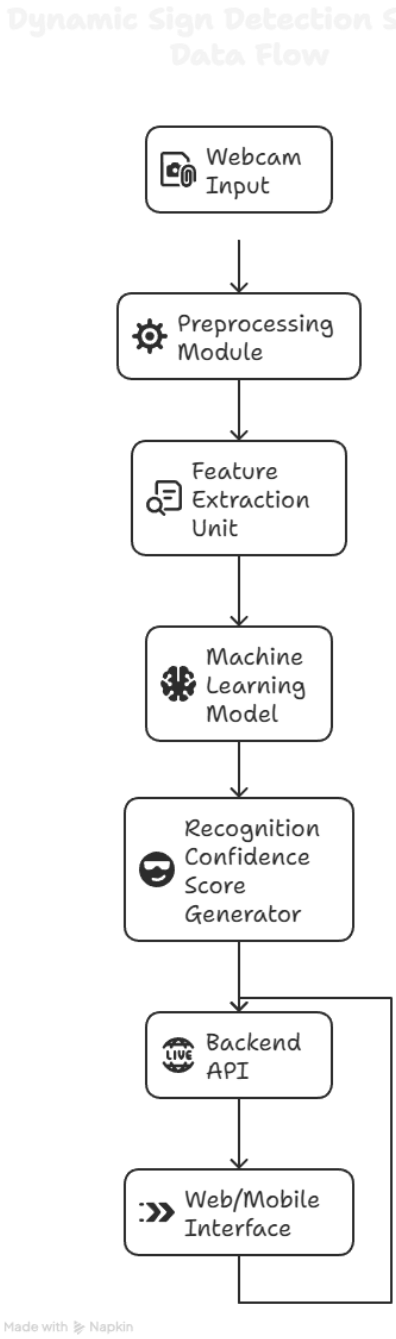

Figure 1-component diagram

1.2 RESEARCH GAP

When analyzing past research on sign language recognition, with a focus on American Sign Language (ASL) and Indian Sign Language (ISL), six notable studies were reviewed. Each contributed toward advancing gesture recognition using computer vision, yet several key limitations were identified, particularly in applicability to Tamil Sign Language (TSL), dynamic gesture handling, real-world adaptability, multimodal integration, explainability, and scalability.

Hand Landmark Tracking for ASL Recognition [11]

This study utilized Mediapipe to track hand landmarks, achieving 86% accuracy in recognizing static ASL gestures. While effective for isolated poses, it focused solely on hand data and did not address the dynamic transitions critical to TSL communication.

LSTM-Based Gesture Sequence Modeling for ISL [12]

A system using LSTM networks modeled temporal sequences in ISL, reporting 91% accuracy for multi-frame transitions. However, it was tested in controlled settings and lacked datasets or adaptations for TSL's unique grammar and gesture fluidity.

Static Pose Recognition Using OpenCV [13]

This research employed OpenCV for static hand pose detection, improving accuracy by 12% under controlled lighting. Its limitation lies in neglecting dynamic gestures and real-world variables like background interference, which are prevalent in TSL usage.

Multimodal Hand Tracking in Controlled Environments [14]

This study combined hand tracking with motion trajectories for ASL, showing promise in gesture classification. However, it was conducted in lab conditions with fixed lighting and limited signer diversity, reducing its relevance to TSL in diverse settings.

Deep CNNs for ASL Gesture Classification [15]

Using deep Convolutional Neural Networks (CNNs), this work achieved 92.6% accuracy on ASL datasets. The "black box" nature of CNNs provided no explainability, posing trust issues for TSL users who need transparent recognition insights.

Sensor-Based Sign Recognition [16]

This approach used specialized sensors and gloves for high-accuracy sign detection. While effective, its reliance on costly hardware limits scalability for TSL users in Sri Lanka, where consumer-grade webcams are more practical.

These studies highlight a significant research gap in TSL recognition, particularly the lack of standardized TSL resources, the focus on static rather than dynamic gestures, the reliance on controlled testing environments, the limited use of multimodal and contextual features, the absence of explainable AI, and the inaccessibility of advanced systems for widespread use in Sri Lanka.

Feature / Gap Dimension	Focus on Dynamic Gestures & Transitions	Real-Time Recognition with Consumer Devices (Webcam)	Robust Preprocessing (Keypoint Extraction, Encoding)	Use of Lightweight ML Models (LSTM/CNN)	Explainable AI & User Trust (SHAP/Feature Importance)

1.3 RESEARCH PROBLEM

The research problem of this project is to determine the feasibility of using a dynamic sign detection system based on computer vision to accurately recognize Tamil Sign Language (TSL) gestures in real time for the hearing-impaired community in Sri Lanka. Specifically, the problem is to explore how subtle markers in hand movements (finger configurations, gesture transitions), spatial dynamics (hand positioning, motion trajectories), and contextual cues (environmental factors, user variability) can be integrated into a robust recognition framework to provide an accessible and reliable interpretation tool. The study also aims to assess the practicality of deploying this system using consumer-grade webcams in home, educational, and public environments, while addressing challenges related to scalability, accuracy, and user adaptability.

The research aims to address the following questions:

- Can computer vision techniques (e.g., OpenCV, Mediapipe) reliably detect and interpret dynamic TSL gestures in non-controlled, real-world settings?
- What are the potential benefits and limitations of using lightweight machine learning models (e.g., LSTM networks, CNNs) for recognizing complex TSL gesture sequences?
- How effective is the integration of transitional movement analysis and contextual data in improving the accuracy of TSL recognition compared to static gesture detection alone?
- What are the usability, scalability, and performance considerations when implementing a dynamic sign detection system using standard webcams in diverse environments?
- How can explainable AI methods (e.g., feature importance analysis) enhance user trust by clarifying which hand or motion features contribute to TSL recognition? By addressing these questions, the research will contribute to the development of a low-cost, scalable, and interpretable TSL recognition solution. The proposed system emphasizes real-time communication support, practical deployment, and community empowerment, offering a pathway toward improved accessibility that complements existing manual interpretation methods.

2. OBJECTIVES

2.1 MAIN OBJECTIVES

To develop a dynamic sign detection system using computer vision that accurately recognizes and interprets Tamil Sign Language (TSL) gestures in real time, enhancing communication accessibility for the hearing-impaired community in Sri Lanka.

2.2 SUB OBJECTIVES

1. Collect and process video input using consumer-grade webcams to capture dynamic TSL gestures, focusing on hand movements and spatial dynamics.
2. Extract hand-based features such as finger configurations, gesture transitions, and hand positioning from video frames.
3. Extract temporal and motion features such as gesture speed, motion trajectories, and transitional fluidity from TSL sequences.
4. Extract contextual metrics including environmental lighting variations, background interference, and user posture adjustments during signing.
5. Apply lightweight machine learning models (e.g., LSTM networks, Convolutional Neural Networks) to classify and detect TSL gesture patterns accurately.
6. Fuse multimodal features into a unified Recognition Confidence Score (0–100) that quantifies the accuracy of TSL gesture interpretation.
7. Incorporate explainable AI techniques (e.g., feature importance analysis, SHAP) to highlight key hand and motion features influencing gesture recognition.
8. Enable user feedback and reporting mechanisms to support real-time adjustments and improve system performance for TSL users.
9. Ensure accessibility and affordability by designing the system to operate on standard webcams and suit home, educational, and public settings.
10. Develop a simple web/mobile interface that provides TSL gesture recognition results and user feedback in an intuitive format.

3. METHODOLOGY

The proposed methodology for this research component involves a structured sequence of steps to achieve the stated objectives. The system will use consumer-grade webcams to collect video input of TSL gestures, process these signals using lightweight machine learning models, and generate a Recognition Confidence Score that reflects the accuracy of gesture interpretation.

The first step is data collection, where video input will be captured through a web/mobile interface. This includes:

- Video recordings of dynamic TSL gestures from various signing tasks (e.g., storytelling, daily conversation).
- Spatial data captured during these tasks to track hand movements, finger configurations, and motion trajectories.
- Contextual data such as environmental lighting conditions, background variations, and user posture adjustments. Publicly available sign language datasets (e.g., ASL datasets adapted for TSL) will also be incorporated to support model training.

Next, data preprocessing will be performed to remove noise and prepare the features. For video data, this includes frame alignment, hand detection, and landmark extraction using Mediapipe to measure hand positions and temporal changes. Contextual data will be normalized to account for lighting and background variations, ensuring robustness across diverse settings.
The third step is feature extraction, where:

- Hand-based features (e.g., finger orientations, gesture transitions, hand positioning).
- Temporal features (e.g., gesture speed, motion trajectories, transitional fluidity).
- Contextual features (e.g., lighting impact, background interference). will be derived and combined into feature sets suitable for machine learning.

The fourth step is model training and testing. Two categories of models will be applied:

- Supervised learning models (LSTM networks, Convolutional Neural Networks) to classify TSL gesture patterns across different signing styles.
- Unsupervised learning models (e.g., clustering techniques) to detect anomalies in gesture sequences that deviate from standard TSL patterns.

Following model evaluation, the system will implement a fusion and scoring module. This module will integrate the outputs of the models into a unified Recognition Confidence Score (0–100). The score will provide a transparent, explainable indicator of gesture recognition accuracy by applying explainable AI (e.g., feature importance analysis, SHAP) to highlight which hand or motion features most influenced each prediction.
Finally, the system will incorporate a user feedback and reporting mechanism. When recognition inaccuracies are detected, users will receive feedback via the web/mobile interface to adjust their signing. The platform will present results in a simple, user-friendly format, providing clear insights into recognition accuracy and contributing factors.

3.1 FEASIBILITY STUDY

3.1.1 TECHNIAL FEASIBILITY

The technical feasibility of this project is high due to the availability of consumer-grade webcams, open-access sign language datasets, and established computer vision frameworks. Video data can be collected through standard webcam input and processed using libraries such as OpenCV and Mediapipe for hand detection, landmark extraction, and motion tracking. Gesture recognition will be supported by tools like TensorFlow and PyTorch, enabling the implementation of lightweight machine learning models such as LSTM networks and Convolutional Neural Networks for accurate classification.

Explainable AI (XAI) techniques, including SHAP and feature importance analysis, will be applied to provide transparency on which hand or motion features drive recognition. Data handling and preprocessing will be managed using Python libraries such as Pandas and NumPy. The web and mobile interface can be developed using cross-platform frameworks like React/React Native or the MERN stack, allowing video input and real-time gesture recognition directly through a browser or mobile device. Deployment can be facilitated through containerized services (Docker/Kubernetes), ensuring scalability and accessibility across platforms.

3.1.2 SECHEDULE FEASIBILITY

Schedule feasibility refers to the project's ability to be completed within the allotted timeframe. For this component, feasibility will depend on the timely availability of sign language datasets, access to consumer-grade webcams, and setup of computer vision frameworks. Possible delays may arise from technical challenges in data preprocessing, model training, or real-time processing optimization.

To minimize risks, a structured project schedule with defined milestones will be prepared, covering tasks such as data collection, feature extraction, model development, and interface design. With proper planning and monitoring, the project can be completed within the expected timeframe.

3.1.3 ECONOMIC FEASIBILITY

This project is economically feasible as it utilizes low-cost consumer-grade webcams and relies on open-source tools and datasets such as OpenCV, Mediapipe, and TensorFlow, minimizing expenses. Deployment through affordable cloud services ensures scalability, making it a cost-effective solution for widespread adoption. The system's design for standard devices and its focus on accessibility in home, educational, and public settings further enhance its economic viability, providing a practical communication tool for the hearing-impaired community.

3.2 SYSTEM ANALYSIS

3.2.1 SOFTWARE SOLUTION APPROACH

- Data Collection:

  Capture video input using consumer-grade webcams to record dynamic TSL gestures during structured signing tasks (e.g., storytelling, sentence formation). Webcams will capture hand movements, finger configurations, and motion trajectories, while contextual data such as lighting conditions and user posture will also be logged. Open-access sign language datasets (e.g., ASL datasets adapted for TSL) will supplement training and validation.

- Pre-processing:

Clean and process video data to remove noise, align frames, and normalize features. This includes hand detection, landmark extraction using Mediapipe, and normalization of contextual data to account for lighting and background variations, ensuring consistency across diverse environments.

.

- Feature Extraction:

  Derive hand-based features (e.g., finger orientations, gesture transitions, hand positioning), temporal features (e.g., gesture speed, motion trajectories, transitional fluidity), and contextual features (e.g., lighting impact, background interference). These features will form the basis for gesture recognition and pattern analysis.

- Model Training:

  Train lightweight supervised models (LSTM networks, Convolutional Neural Networks) to classify TSL gesture patterns, and use unsupervised models (e.g., clustering techniques) to detect anomalies in gesture sequences that deviate from standard TSL patterns.

- Model Evaluation:

  Evaluate models using accuracy, precision, recall, and F1-score, supported by cross-validation to reduce overfitting and ensure generalization across different signing styles and environments.

- Recognition Confidence Score Generation:

  Fuse outputs from all models into a single Recognition Confidence Score (0–100), quantifying the accuracy of TSL gesture interpretation. Explainable AI methods (e.g., SHAP, feature importance analysis) will be applied to highlight key hand and motion features influencing each prediction.

- User Feedback System:

  Implement a feedback mechanism to notify users when recognition inaccuracies occur, enabling real-time adjustments to improve signing accuracy and system performance.

- Web/Mobile Application Integration:

  Develop a cross-platform interface using React/React Native that allows users to perform signing tasks, view recognition results, and provide feedback, with clear, user-friendly visualizations tailored to the hearing-impaired community.

- User Experience Design:

  Ensure accessibility for TSL users by integrating large icons, simple navigation, high-contrast visuals, and minimal text complexity to accommodate diverse user needs.

- System Deployment:

  Deploy the backend and models using containerized services (Docker/Kubernetes) on a secure cloud platform, enabling real-time processing, scalability, and reliable storage of gesture data and recognition history.

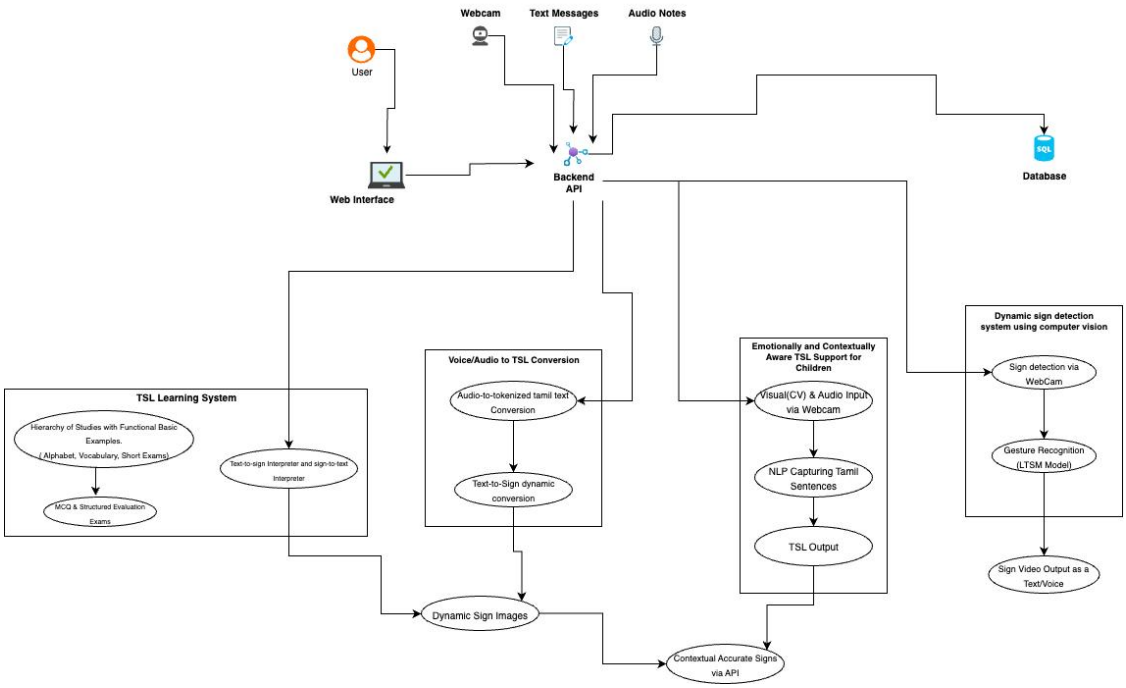

Figure 2-System Architecture diagram

3.2.2 TOOLS & TECHNOLOGY

Table 2-Tools

Category	Technologies and Tools	Purpose
Hardware	Consumer-grade webcams	Capture video input of TSL gestures

Computer Vision	OpenCV, Mediapipe,	Frame processing, hand detection, preprocessing (OpenCV), Landmark extraction, motion tracking (Mediapipe)
Machine Learning	Whisper (ASR), TensorFlow, PyTorch	Alternative framework for model development (Pytorch), Training LSTM and CNN models (TensorFlowc)
Data Processing	Pandas	Data handling and preprocessing
Frontend Development	React/React Native	Cross-platform web/mobile interface
MobileApp Development/Web Development	Flutter.React.JS	Alternative framework for mobile app development Alternative framework for mobile app development
Backend Development	Node.js,SpringBoot	Backend API for real-time processing

Data Storage	MongoDB (session data), Cloud Storage (AWS/GCP for media)	storage of user sessions and recognition history
Deployment	Docker, Kubernetes, Nginx	Containerized deployment for application modules
Security	HTTPS, JWT Authentication, Flask-Talisman	Secure data transmission over the internet
Version Control	Git, GitHub	Centralized repository and collaboration platform
Collaboration	Google Meet,WhatsApp	Instant messaging for team communication
Project Management	Trello, Jira	Issue tracking and agile project management

3.3 RESEARCH REQUIREMENTS

This project involves developing a non-invasive, dynamic sign detection system using computer vision that integrates video data to recognize and interpret Tamil Sign Language (TSL) gestures in real time, generating a Recognition Confidence Score for accurate communication support. The system will capture real-time video input through consumer-grade webcams, supplemented by open-access sign language datasets (e.g., ASL datasets adapted for TSL).

The collected data will undergo preprocessing (frame alignment, hand detection, landmark extraction) and feature extraction (finger orientations, gesture transitions, motion trajectories, lighting impact). Lightweight machine learning models such as LSTM networks, Convolutional Neural Networks, and clustering techniques will be applied for gesture classification and anomaly detection. Model explainability will be incorporated using SHAP to provide transparent insights into feature importance.

The platform will include a web/mobile application where users can perform signing tasks, and educators or caregivers can access recognition results, reports, and feedback. A user feedback system will be integrated to ensure real-time adjustments when recognition inaccuracies are detected.

The project covers data collection, preprocessing, feature extraction, model training and evaluation, recognition scoring, system integration, interface design, deployment, and usability testing. The system will be tested to ensure accuracy, interpretability, and accessibility.

The goal is to deliver a cost-effective, user-friendly, and scalable communication tool that enhances TSL recognition and empowers the hearing-impaired community with improved access to education and daily interactions.

.

3.3.1 FUNCTIONAL REQUIREMEMNTS

Functional requirements define the core features and capabilities that the system must provide to achieve its intended purpose. For this component, the functional requirements include:

- **Data Collection**: Capturing video input using consumer-grade webcams to record dynamic TSL gestures, including hand movements, finger configurations, and motion trajectories. Supplementary open-access sign language datasets (e.g., ASL datasets adapted for TSL) will also be utilized.
- **Data Preprocessing**: Processing raw video data, including frame alignment, hand detection, landmark extraction using Mediapipe, and normalization of contextual factors such as lighting and background variations.
- **Feature Extraction**: Deriving measurable attributes from video input—hand-based features (finger orientations, gesture transitions, hand positioning), temporal features (gesture speed, motion trajectories, transitional fluidity), and contextual features (lighting impact, background interference).
- **Model Training & Testing**: Implementing lightweight supervised models (LSTM networks, Convolutional Neural Networks) for TSL gesture classification and unsupervised models (clustering techniques) for anomaly detection in gesture sequences.
- **Recognition Confidence Score**: Integrating multimodal model outputs into a unified Recognition Confidence Score (0–100) that quantifies the accuracy of TSL gesture interpretation.
- **Explainability Module**: Applying SHAP to provide interpretable insights into which hand and motion features most influenced gesture recognition predictions.
- **User Feedback System**: Generating notifications for users when recognition inaccuracies are detected, enabling real-time adjustments to improve signing accuracy.
- **Web/Mobile Application Interface**: Providing a user-friendly interface for the hearing-impaired to perform signing tasks and for educators or caregivers to access recognition results, reports, and feedback.
- **User Accessibility Features**: Incorporating large icons, simplified navigation, high-contrast visuals, and minimal text complexity to ensure ease of use for the hearing-impaired community.

3.3.2 NON-FUNCTIONAL REQUIREMENTS

Non-functional requirements describe the quality attributes and constraints that govern how the system should operate. For this component, they include:

- **Performance**: The system should process video input and generate recognition scores in near real time to support seamless communication without noticeable delays.
- **Reliability**: The system must consistently produce accurate and stable recognition results when analyzing video data, ensuring dependable TSL interpretation.
- **Security**: All sensitive video data must be encrypted in transit and at rest, with strict access control to protect user privacy.
- **Scalability**: The platform should support increasing numbers of users, concurrent video uploads, and larger datasets without performance degradation.
- **Usability**: The interface should be simple, intuitive, and hearing-impaired-friendly, with large icons, clear visuals, and easy navigation for users and educators/caregivers.
- **Availability**: The system should maintain high uptime to ensure continuous access to gesture recognition and reliable user feedback.
- **Compatibility**: The web/mobile application should run smoothly across major browsers and operating systems, supporting common consumer-grade webcams.
- **Maintainability**: The architecture and codebase should allow easy debugging, modular updates, and integration of improved models or new datasets.
- **Explainability**: Model predictions must be interpretable using SHAP, allowing users and educators to understand which features influenced recognition accuracy.

3.4 TEST

Testing will be a critical phase to ensure the reliability, accuracy, and usability of the proposed Dynamic Sign Detection System. The initial plan is to conduct functionality testing within the development team and close associates, simulating real-world video-based TSL gesture inputs. This stage will primarily involve unit testing and integration testing to verify that individual modules, such as data collection, preprocessing, feature extraction, and model inference, work

correctly together. In the final phase of the research, the system will be tested with a selected group of hearing-impaired participants and educators/caregivers, first in a controlled environment and later in a real-world deployment setting. This stage will include acceptance testing, with Alpha testing to gather user feedback on usability and accessibility, followed by Beta testing to evaluate live performance, user feedback notifications, and explainability outputs. Testing will include both manual and automated methods. Manual testing will verify user interface accessibility (large icons, simple navigation), the accuracy of Recognition Confidence Score presentation, and the effectiveness of user feedback alerts. Automated tests will use predefined sign language datasets and assert functions to validate the accuracy of machine learning models, consistency of gesture recognition, and correctness of feedback triggers. Special emphasis will be placed on ensuring that the system provides consistent results across different devices, browsers, and network conditions, while maintaining privacy and security of sensitive video data.

5. BUDGET AND BUDGET JUSTIFICATION

Table 3-Budget

Category	Budget (LKR)
Data Collection	4,000.00
Software Development	4,500.00
Testing and Validation	4,500.00
System Deployment	2,500.00
Total	**15,500.00**

The total estimated budget for the Tamil Sign Language (TSL) Audio-to-Sign Conversion System is LKR 15,500, carefully distributed across four main categories. This allocation ensures the successful collection of data, development of the system, testing, and deployment in real-world contexts.

1. Data Collection - LKR 4,000

The system requires high-quality Tamil speech data and corresponding Tamil Sign Language gesture datasets for training and validation. Since TSL resources are limited, part of this budget will be used for curating datasets through collaboration with educators, deaf schools, and community experts. Additional costs may include transcription, annotation, and basic preprocessing of audio and gesture recordings.

2. Software Development - LKR 4,500

The development stage includes:

- Implementing the speech recognition module (local ML-based ASR trained on Tamil datasets).
- Training logistic regression models for mapping tokenized Tamil text to TSL gestures.
- Developing a user-friendly API to connect the backend modules with the frontend interface.
- Designing the frontend application using React.js to visualize real-time gesture outputs.
- Backend integration through frameworks like Spring Boot with MySQL for database management.

This budget ensures the availability of development tools, libraries, and potential costs for external APIs during prototyping.

3. Testing and Validation - LKR 4,500

Testing is crucial to evaluate system accuracy, performance, and usability. This includes:

- Accuracy checks on speech-to-text recognition under different accents and noisy conditions.
- Validation of gesture prediction outputs for linguistic correctness.
- User acceptance testing with members of the Tamil-speaking hearing-impaired community.
- Iterative improvements based on feedback from educators and accessibility experts.

This allocation also covers logistical expenses for user trials and validation sessions.

4. System Deployment – LKR 2,500

Deployment involves hosting the system on a secure and scalable platform. Hosting may include:

- Cloud deployment with API integration for easy accessibility.
- Providing access to schools, NGOs, and public organizations supporting hearing-impaired communities.
- Basic maintenance and monitoring of the deployed system to ensure reliability.

The allocation ensures that the system is accessible to its target audience in real-world settings.

This budget allocation of LKR 15,500 strikes a balance between research rigor and resource efficiency. By prioritizing lightweight models and scalable software design, the system remains affordable while maintaining academic and practical value. The distribution emphasizes data quality, robust software development, extensive testing, and accessible deployment, ensuring that the Tamil Audio-to-TSL system is not only technically sound but also socially impactful.

6.WORK BREAKDOWN STRUCTURE

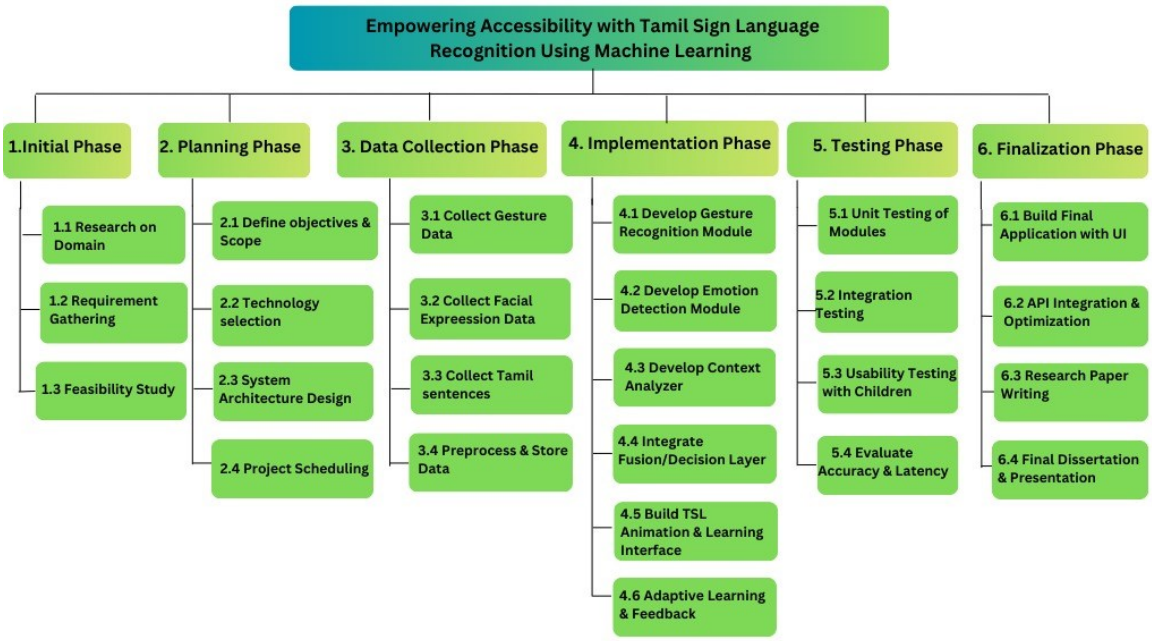

Table 4-WBS

7. GANTT CHART

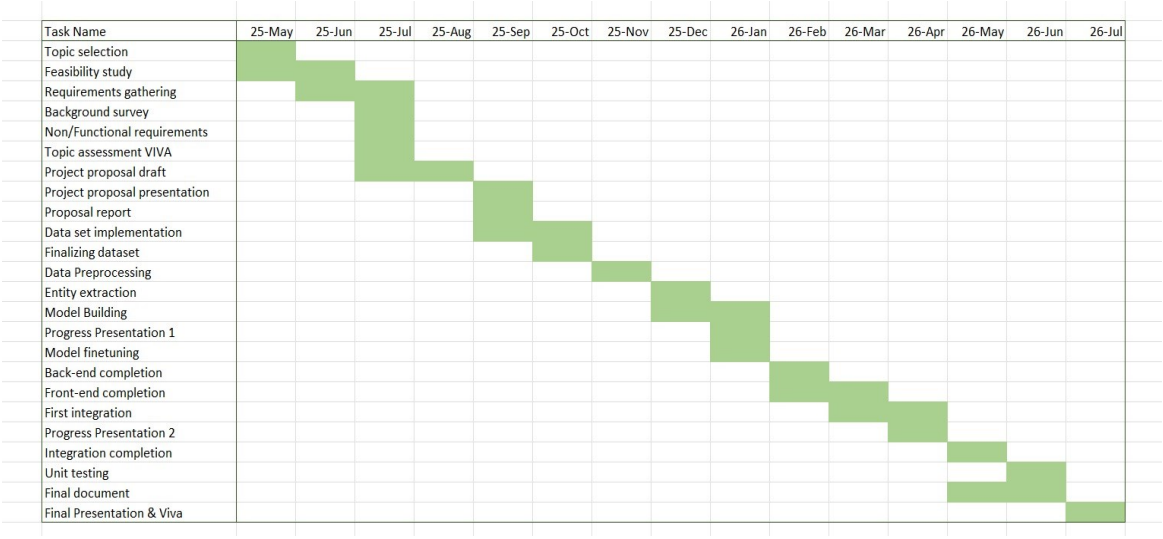

Table 5 - Gantt chart

8. COMMERCIALIZATION

The commercialization potential of this component lies in its ability to provide an affordable, non-invasive, and explainable TSL gesture recognition solution using widely available consumer-grade webcams. By enabling real-time interpretation of dynamic TSL gestures, the system addresses a critical communication challenge for the hearing-impaired community in Sri Lanka and beyond. This solution can be marketed to educational institutions, NGOs supporting the hearing-impaired, sign language training centers, tele-education providers, and community organizations as a low-cost, AI-assisted communication and learning platform. It can be offered as:

- A subscription-based web/mobile application for hearing-impaired individuals, educators, and families to facilitate daily communication and learning at home or in classrooms.
- A white-labeled platform licensed to educational technology companies, accessibility service providers, and technology vendors for integration into their offerings.
- An integrated service embedded within existing tele-education platforms, special education programs, or community inclusion initiatives.

The system's reliance on consumer-grade webcams makes it highly scalable and cost-effective for both urban and rural settings in developed and developing regions. Strategic partnerships with government education departments, NGOs, and technology firms specializing in accessibility can accelerate adoption and broaden access.

Effective commercialization strategies will focus on:

1. Demonstrating educational and social benefits by improving communication access, reducing reliance on human interpreters, and enhancing learning opportunities for the hearing-impaired.
2. Emphasizing usability and accessibility, showcasing how elderly-friendly and intuitive design, along with explainable outputs, boosts user confidence and adoption.
3. Leveraging digital marketing and B2B outreach to target both individual users and institutional markets, such as schools and community centers.
4.

By addressing both direct-to-consumer and B2B accessibility segments, this component has the potential to become a sustainable, revenue-generating product that delivers meaningful social impact by empowering the hearing-impaired community with improved communication and educational tools
